De ict-revolutie van de afgelopen tien jaar lijkt voorbijgegaan aan de gebouwtechniek. Deerns probeert de achterstand in te lopen met een...

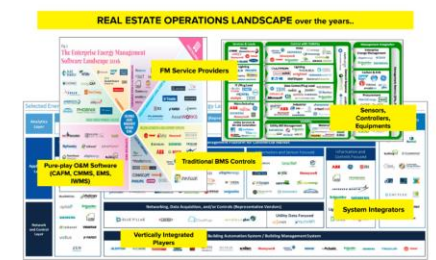

1 – WE'RE STARTING WITHOUT A CLEAR DEFINITION OF THE PROBLEM

- + The 'WHY' is not clear (what problem are we solving?)
- + the means justify the ends

2 – LEARN HOW TO WALK BEFORE WE START RUNNING

- + "70% of building management systems are not properly configured (and therefore do not operate optimally).
- + Research indicates that 80% of buildings already have the capabilities that the Facility Manager desires."

3 - SMART BUILDINGS ARE NOT SCALEBLE

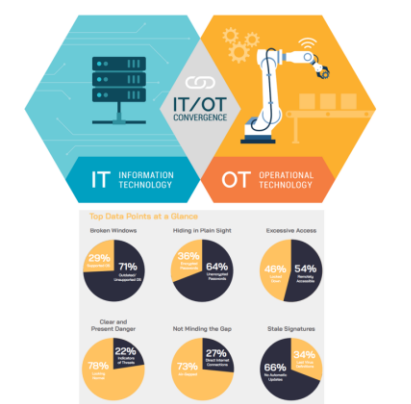

- + "The ecosystem of most suppliers is closed.
- + Each building is unique (in age, manufacturers, protocols)."

4 – DE REAL ESTATE DATA IS OFTEN INCORRECT OR NOT AVAILABLE

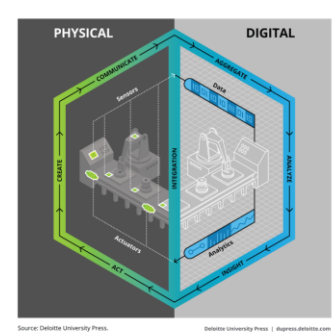

- + So many standards
- + The installations operate independently from each other (And data is not being reused)

“ 7 REASONS WHY YOU SHOULD NOT START WITH A SMART BUILDING,,

5 – THE RISKS OF CYBERSECURITY ARE INCREASING

1. The potential attack surface is expanding
 - Target1
2. OT SYSTEMS are old
 - 71% heeft verouderde of niet-ondersteunde besturingssystemen2

6 – WE DO NOT CLOSE THE CIRCLE

- + We elevate the means to the goal: a smart building is not about technology.
- + The resources don't make a building smart; it's the end result that does

Goal of this handbook

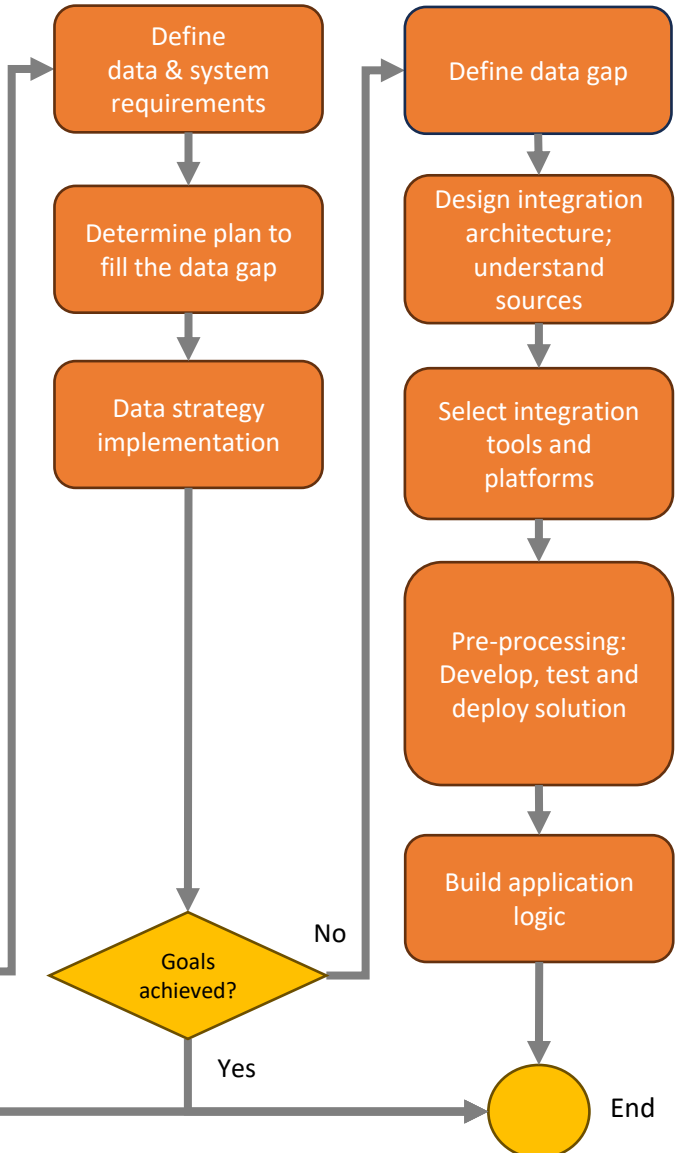

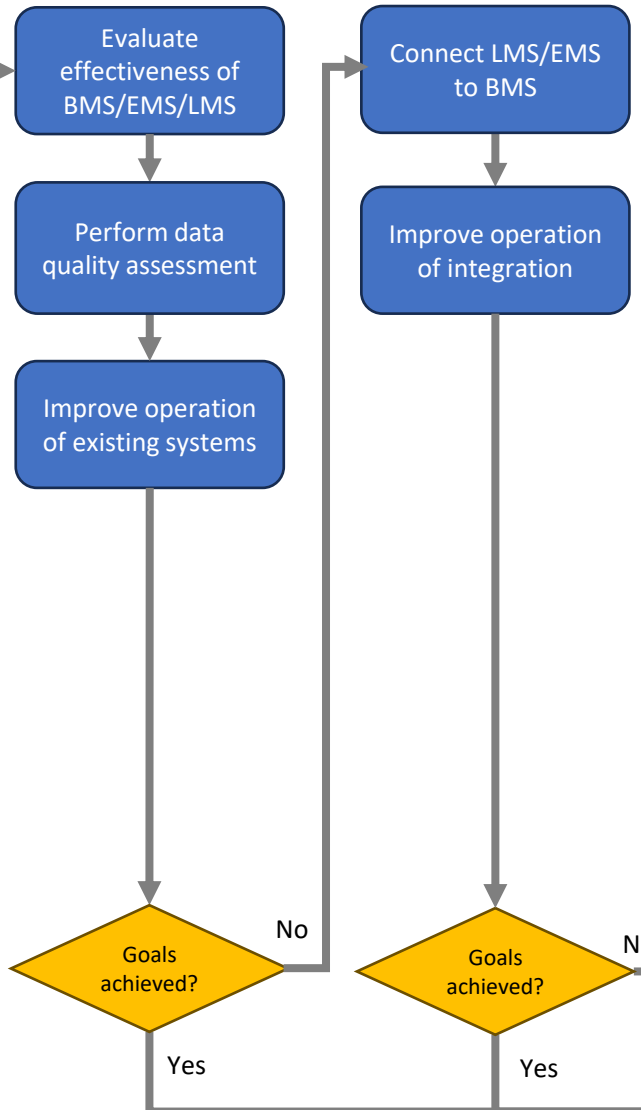

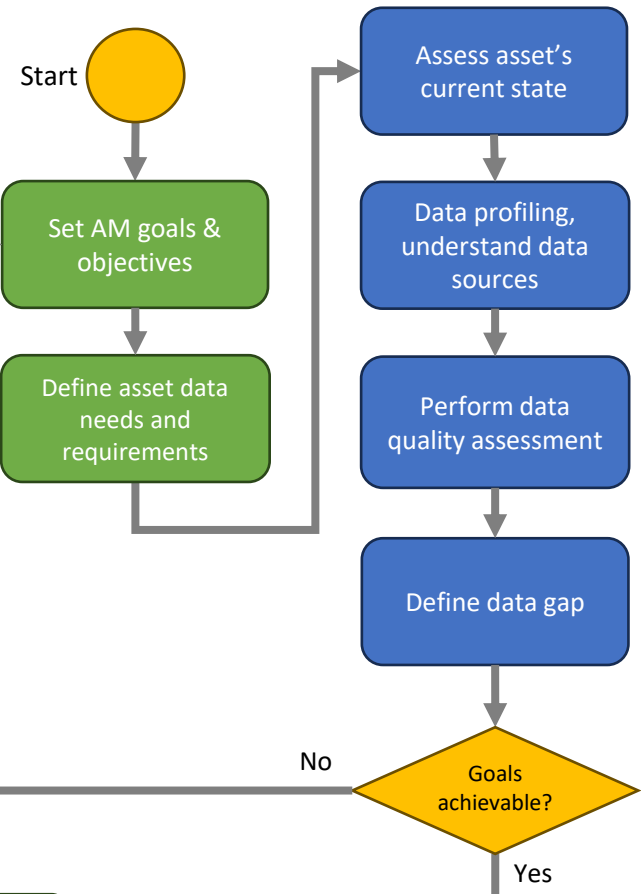

1. Create **awareness** about the current challenges in the industry and how they can be overcome with both **high-tech** and **low-tech** solutions;
2. Illustrate that a smart building is a **tool** and not a goal in itself to achieve a (set of) predefined asset management **goal(s)**;
3. Provide the different stakeholders in the smart building value chain with a **practical roadmap** for achieving asset management goals through data-driven solutions, by starting with **data integration**.

“Help the customer to define and prioritize her ambitions (goals & objectives),,,

Strategy & Policy

Level: Strategic

What: Organizational strategic plans and policy documents

Why: For effective asset management it is essential to align the AM goals and objectives with the organization's strategic plans.

Who: Defined usually by the board of directors and/or the asset owner.

AM goals, objectives and plan

Level: Strategic / Tactic

What: SAMP (Strategic Asset Management Plan) and AMP (Asset Management Plan)²

Why: SAMP is used to translate the organizational goals into AM goals and objectives. AMP is used to describe the activities and planning needed to realize the AM goals and objectives.

Who: Put together by the asset owner or asset manager, with possible input from the facility manager.

Information Requirements

Level: Tactic / Operational

What: AIR (Asset Information Requirements)³

Why: The organization needs to define its AIR to support its AM activities, systems and the achievement of its organizational and AM goals and objectives.

In doing that, it is important to ensure that there is consistency and traceability between the different types of data.

Who: Asset and facility managers should draft the AIR and use them to define exchange information requirement in projects/contracts with service providers.

Set your goals

Smart building capabilities are defined by the combination of data driven insights and analytics. These data driven insights are used to optimize the building's performance and reduce costs.

Asset Management (AM) describes the defined processes and activities that are used to manage the assets. What value does the asset generate? What are the specific objectives and needs associated with the asset?

Define the value of the assets. The asset's value is determined by the asset's condition and the AM and the asset's lifecycle. The asset's value is determined by the asset's condition and the AM and the asset's lifecycle. The asset's value is determined by the asset's condition and the AM and the asset's lifecycle.

Set AM goals & objectives

What does this step mean? Setting up AM goals and objectives is a key step in the asset management process. It involves defining the asset's value and the asset's lifecycle. The asset's value is determined by the asset's condition and the AM and the asset's lifecycle. The asset's value is determined by the asset's condition and the AM and the asset's lifecycle.

Why do we need it? The asset's value is determined by the asset's condition and the AM and the asset's lifecycle. The asset's value is determined by the asset's condition and the AM and the asset's lifecycle. The asset's value is determined by the asset's condition and the AM and the asset's lifecycle.

What are the conditions and requirements to be met? The asset's value is determined by the asset's condition and the AM and the asset's lifecycle. The asset's value is determined by the asset's condition and the AM and the asset's lifecycle. The asset's value is determined by the asset's condition and the AM and the asset's lifecycle.

Define asset data needs & requirements

What does this step mean? The asset's data needs and requirements are defined by the asset's value and the asset's lifecycle. The asset's value is determined by the asset's condition and the AM and the asset's lifecycle. The asset's value is determined by the asset's condition and the AM and the asset's lifecycle.

Why do we need it? The asset's data needs and requirements are defined by the asset's value and the asset's lifecycle. The asset's value is determined by the asset's condition and the AM and the asset's lifecycle. The asset's value is determined by the asset's condition and the AM and the asset's lifecycle.

What are the conditions and requirements to be met? The asset's data needs and requirements are defined by the asset's value and the asset's lifecycle. The asset's value is determined by the asset's condition and the AM and the asset's lifecycle. The asset's value is determined by the asset's condition and the AM and the asset's lifecycle.

Example SRI

The Smart Building Index (SBI) is a key metric developed by the European Commission. It is used to measure the performance of smart buildings. The SBI is defined by the asset's value and the asset's lifecycle. The SBI is defined by the asset's value and the asset's lifecycle.

The SBI is defined by the asset's value and the asset's lifecycle. The SBI is defined by the asset's value and the asset's lifecycle. The SBI is defined by the asset's value and the asset's lifecycle.

Define asset data needs & requirements

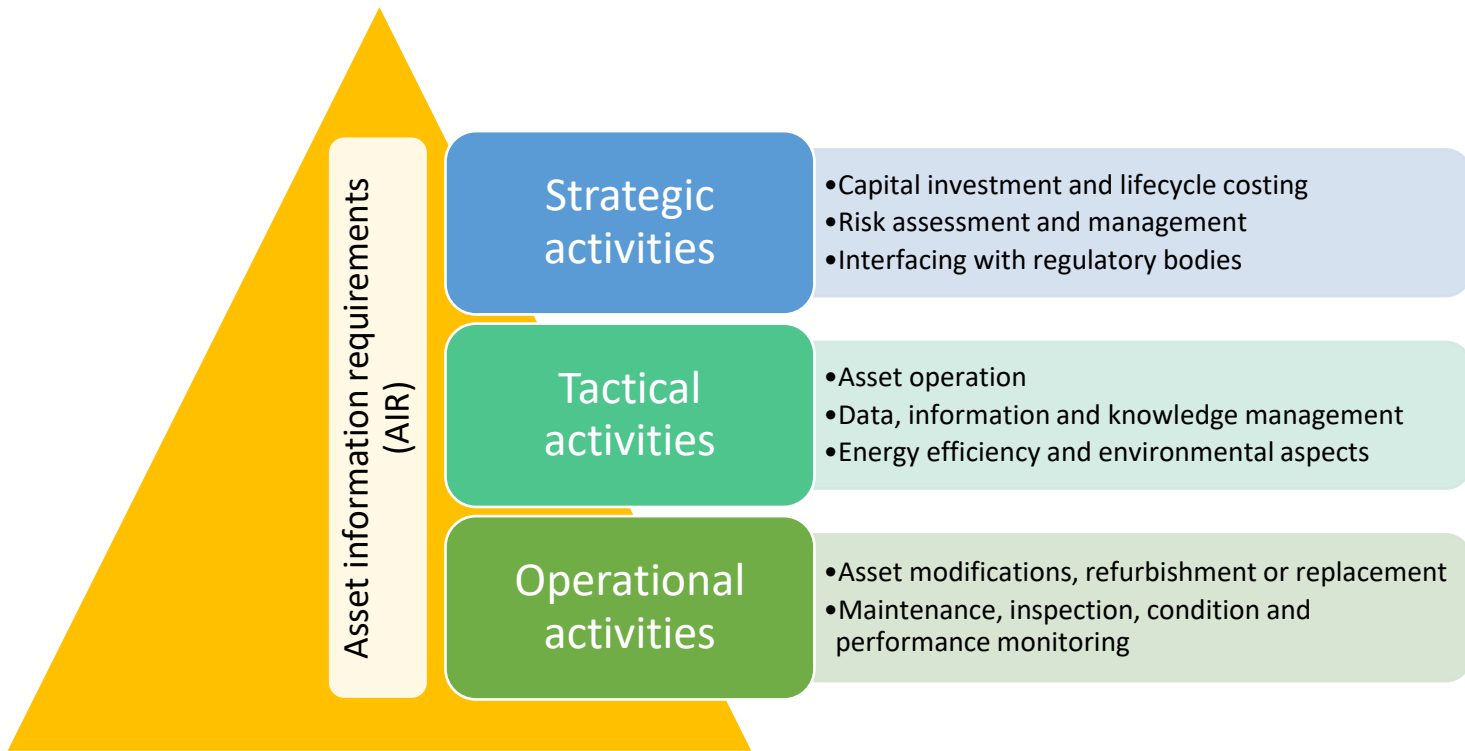

The asset information requirements (AIR) are intended to support the strategic, tactical and operational asset and facility management activities of the organization. They serve as a backbone and guideline for future project activities and the drafting of request for proposal documents.

Strategic activities: Capabilities and services that are essential for the organization's long-term success.

Tactical activities: Assets, systems and services that are essential for the organization's short-term success.

Operational activities: Assets, systems and services that are essential for the organization's day-to-day operations.

“and translate those ambitions into clear asset data needs & requirements,,

Evaluate Set your goals

Smart building capabilities are tested against high value through the collection and analysis of data from various systems. These data are used to integrate and analyze the smart building performance.

Asset Management (AM) describes the condition, performance, and cost of an asset. It is a process that involves the collection, analysis, and interpretation of data to assess the value of an asset and its components. The value of an asset is determined by its condition, performance, and cost. The value of an asset is also determined by its location, its history, and its future potential.

The value of an asset is determined by its condition, performance, and cost. The value of an asset is also determined by its location, its history, and its future potential.

Evaluate Set AM goals & objectives

Setting up AM goals is a critical step in the process of asset management. It involves defining the specific objectives that the organization wants to achieve through its AM efforts. These objectives should be aligned with the organization's overall strategy and should be measurable, achievable, and time-bound.

The goals and objectives of an AM program should be defined in a way that is clear and concise. They should be specific and measurable, and they should be achievable and time-bound. The goals and objectives should also be aligned with the organization's overall strategy and should be measurable, achievable, and time-bound.

Evaluate Define asset data needs & requirements

The asset data requirements (ADR) include the data needed to support the various activities of an AM program. These requirements are defined based on the specific needs of the organization and the data available from various sources.

The ADR should be defined in a way that is clear and concise. They should be specific and measurable, and they should be achievable and time-bound. The ADR should also be aligned with the organization's overall strategy and should be measurable, achievable, and time-bound.

Evaluate Example SRI

The Smart Building Index (SBI) is a key metric used to evaluate the performance of smart buildings. It is a composite index that takes into account various factors such as energy efficiency, environmental impact, and occupant health and well-being.

The SBI is a key metric used to evaluate the performance of smart buildings. It is a composite index that takes into account various factors such as energy efficiency, environmental impact, and occupant health and well-being.

Evaluate Define asset data needs & requirements

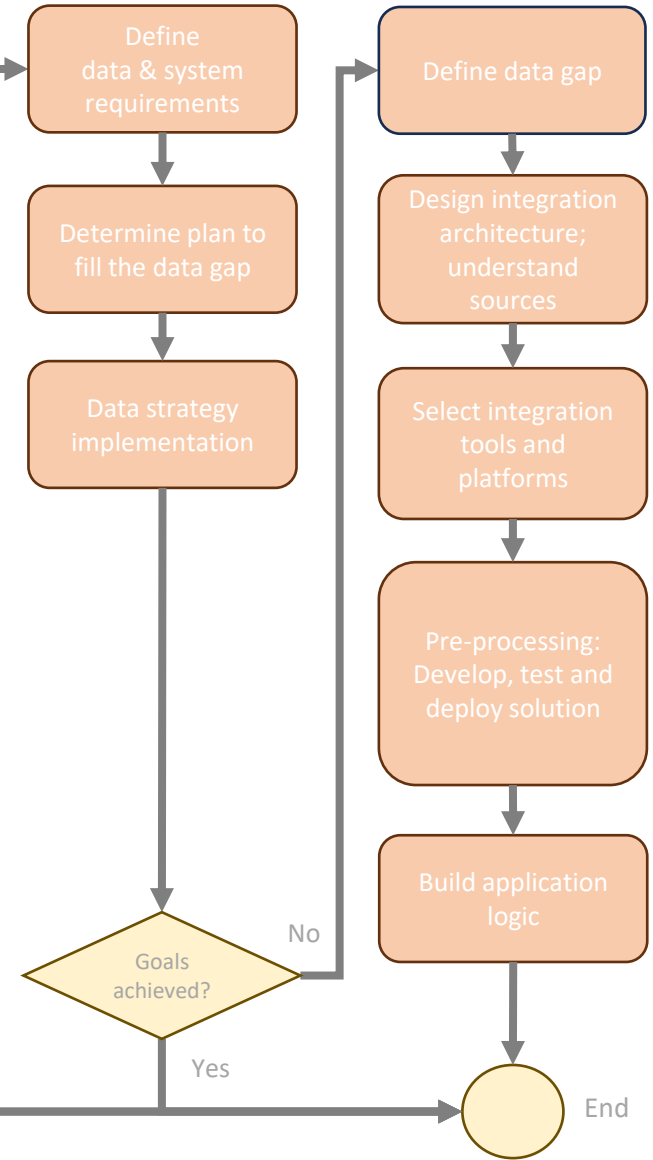

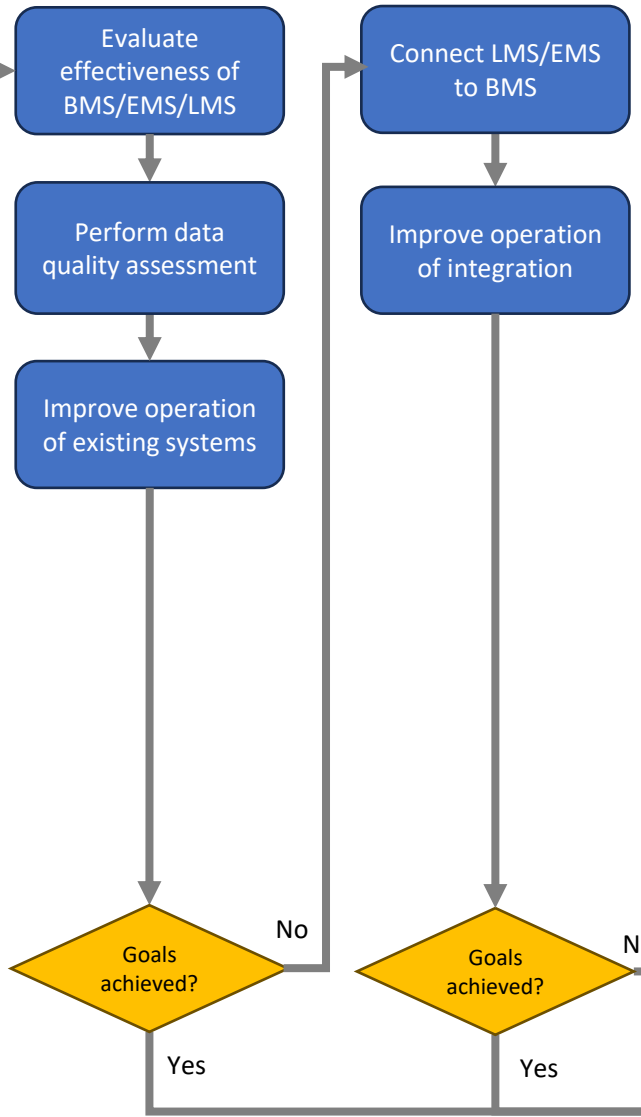

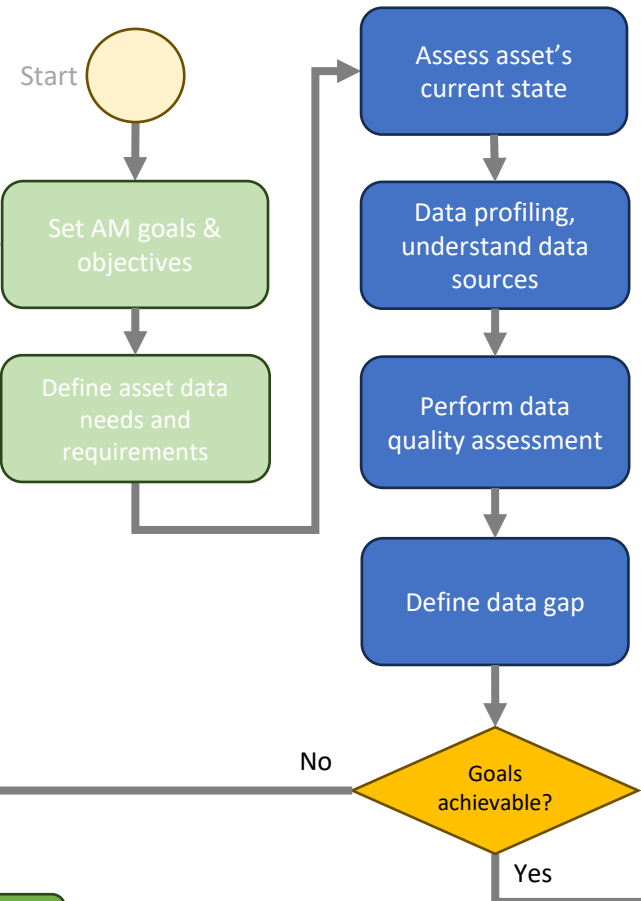

The asset information requirements (AIR) are intended to support the strategic, tactical, and operational activities of an AM program. These requirements are defined based on the specific needs of the organization and the data available from various sources.

The AIR should be defined in a way that is clear and concise. They should be specific and measurable, and they should be achievable and time-bound. The AIR should also be aligned with the organization's overall strategy and should be measurable, achievable, and time-bound.

Evaluate

Improve

Integrate

Legend

- Goals (Green box)
- Existing systems (Blue box)
- New systems (Orange box)

“Evaluate (and optimize) the effectiveness of existing systems (BMS)”

70% van koelinstallaties werkt niet optimaal

Een goed ingeregeld klimaatstelsel houdt het binnenklimaat aangenaam. Ongeveer 70% van de klimaatinstallaties werkt niet optimaal. Een kwart gebruikt te veel energie. Bijvoorbeeld doordat leidingen niet geïsoleerd zijn. Hier is veel energiewinst te halen.

Evaluate Assess asset s state

What do we mean with this step?
 In this step it is necessary to determine which systems the asset possesses that are capable of potentially unlocking useful data. And whether these systems are available when needed. If the goal set in the previous step. Often we see that following systems: the Building Management System (BMS), an Energy Management System (EMS), a Safety Management System (SMS), a Light Management System (LMS), specific sensors that provide insights. The main objective is to make a list of assets and the potential data sources that can be used to achieve the set goal(s).

Why do we need it?
 It is important because in this step we develop the framework upon which we will build our data management strategy.

Who needs to do it?
 The information manager (which should be selected by the owner/asset manager responsible for the asset). Although in the responsible the retailer's & technicians will have a lot of this information.

Evaluate Assess asset s state

What are the conditions and requirements to execute on?
 To make this step executed successfully you need all the information that is available regarding the systems in the asset. This can be a BIM model, CAD drawings, asset lists, data log diagrams and schematics used in the design and construction of the asset etc. It is important that it is clear with respect to this step (often many different stakeholders have a large number of information and the end result should be a list of assets and the (potential) data they can produce.

Who needs to do it?
 The information manager (which should be selected by the owner/asset manager responsible for the asset). Although in the responsible the retailer's & technicians will have a lot of this information.

Evaluate Evaluate effectiveness of BMS/EMS/LMS

What does this step mean?
 This step consists of 3 sub-steps, but they all have the same purpose: to optimize the current management systems which are in place to make sure the building is operating optimally. Evaluate effectiveness: evaluate whether the current management systems are working as they supposed to optimize the systems.

Why do we need it?
 In the Netherlands 70% of comfort systems are not performing optimally. As a result, energy consumption is high, which is not the goal of building management systems. Energy consumption is high because during the design of a building, specific occupancy and function are assumed. However, these often change over time, resulting in the building not being tailored to the energy function and occupancy. An analysis of many building management systems in use in building reveals that 50% of the energy consumption of the BMS (mean value) is due to the wrong use of the building. The energy consumption of the BMS is not optimal. The result is an energy saving of approximately 10% between 5% and 10%.

What are the conditions and requirements to execute on?
 The following steps are important for the execution:
 Make sure the right skills are in place (to optimize a BMS you need specific skills, these are either skills that you can acquire or you need to hire).
 Make sure the function is clear for the building. What are the performance times that are the expected performance of the building etc. This will be the input to optimize the management systems.

Evaluate Connecting assets

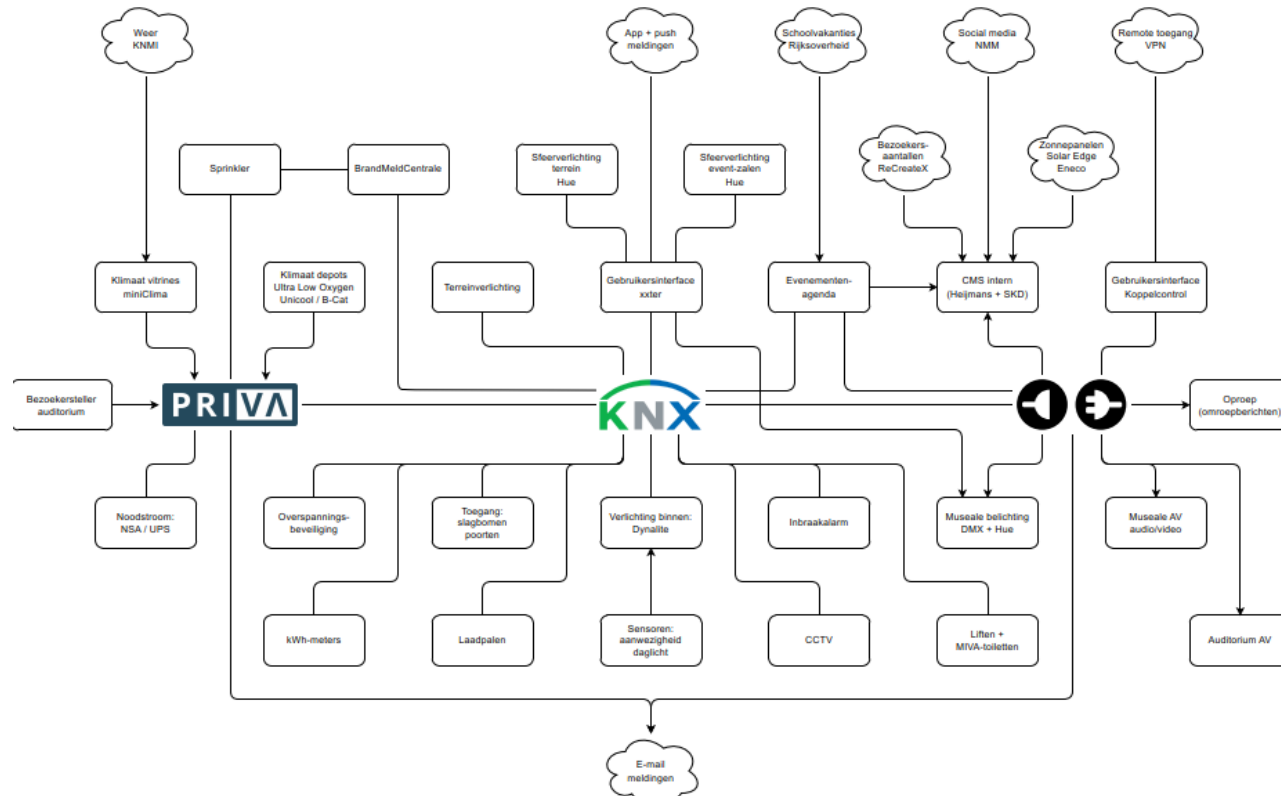

What does this step mean?
 A building has many stand-alone operating systems (like a lighting installation, a fire alarm, etc.). Connect these existing systems with other systems, new systems to the building has to be a very interesting name to optimize the building and realize the goal you have.

Why do we need it?
 This step is important because it is very difficult to effect the way to optimize the performance of the building. And the effective and smart and easy step by step working with building any new systems in the building.

What are the conditions and requirements to execute on?
 To execute this step it is important to understand what assets you have and how they can contribute to the building. This requires knowledge of the individual assets and what they can achieve. Create value. The more you know about the data of the assets, the more you know about the value they can create.

Who needs to do it?
 The hardware vendor of the BMS service provider can help you with this step. Specific terms (lighting, energy) the specialist needs to be consulted.

"Pick the low-hanging fruit"

Evaluate Assess asset s state

What do we mean with this step?

In this step it is necessary to determine which systems the asset possesses that are capable of potentially unlocking useful data. And whether the systems are available which are needed if the goal is set in the previous step. Often we see go the following systems: the Building Management System (BMS), an Energy Management System (EMS), a Safety Management System (SMS), a Light Management System (LMS), specific sensors, and other things.

The main objective is to find out what assets and the potential data sources that can be used to achieve the set goal(s).

Why do we need it?

It is important because in this step we develop the framework upon which we will build our data management strategy.

Evaluate Assess asset s state

What are the conditions and requirements for its execution?

To make sure this step is executed successfully you need all the information that is available regarding the systems in the asset. This can be a BIM model, CAD drawings, asset lists, detailed diagrams, and schematics used in the design and construction of the asset, etc. It is important that it is clear with whom you can get this step (often many different stakeholders) and who has the information and the data they can produce.

Who needs to do it?

The information management which should be selected by the owner/asset manager depends on the asset. Although it is especially the technical areas will have a lot of this information.

mp ve Evaluate effectiveness of BMS/EMS/LMS

What does this step mean?

This step consists of sub-steps, but they all have the same purpose: to determine the current management systems which are in place to make sure the building is operated properly. Evaluate effectiveness: evaluate whether the current management systems are working as supposed to perform and so it makes sure the data quality is good enough for the systems.

Why do we need it?

In the Netherlands 70% of comfort systems are not performed. Although it cannot be said that the building management systems are not properly configured. This is also because during the design of a building, specific occupancy and function are assumed. However, these often change over time, resulting in the building not being fully utilized. The energy management function and occupancy.

An analysis of many building management systems in use in the building reveals that many of the building BMS (management and control) are not working properly. This means that the building is not being operated in an energy-saving manner, resulting in a cost of 5% to 10%.

What are the conditions and requirements for its execution?

The following steps are important for the execution:

- Make sure the right skills are in place to perform a BMS user specification checklist (these are other skills than programming management systems).
- Make sure the function of the building is clear. What are the permitted uses, what are the equipment for functions of the building, etc. This will be the input to the management systems.

mp ve Connecting assets

What does this step mean?

A building has many stand-alone systems (glaziers, installers, etc.). Connect these existing systems with additional new systems to the building has to be a very interesting name to perform the building and make the building better.

Why do we need it?

This step is important because it is a very effective way to perform the performance of the building. And the effort is a very smart and easy step to perform with the building of new systems in the building.

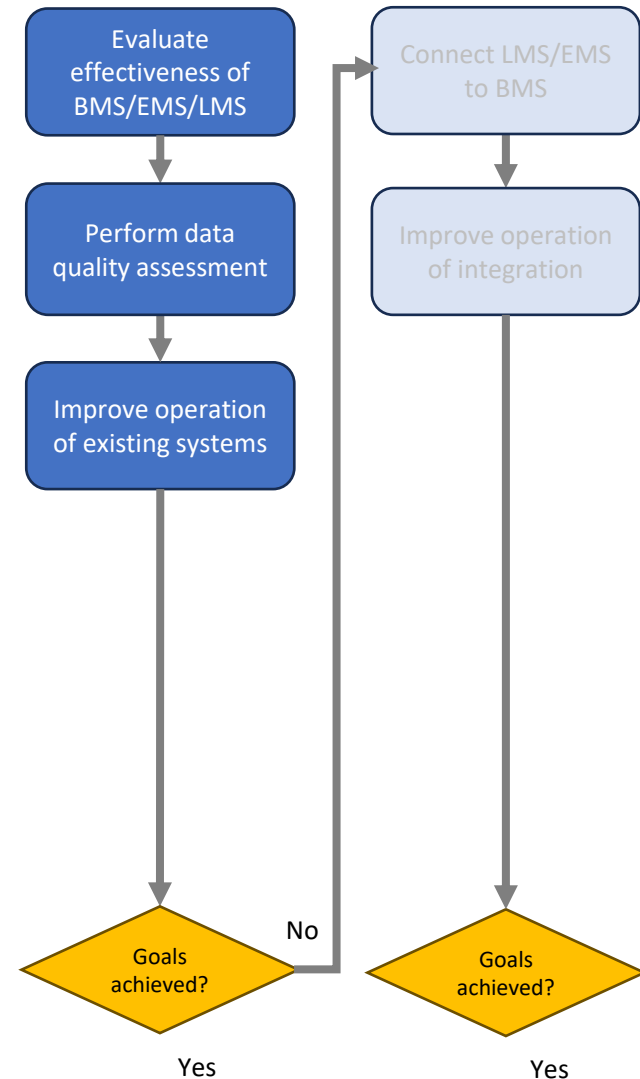

What are the conditions and requirements for its execution?

To execute this step it is important to understand what assets you have and how they can be combined. This requires knowledge of the individual assets and what they can achieve. Create a value.

Who needs to do it?

The hardware vendor of the BMS service provider can help you with this step. Specific terms (lighting, energy) the specialist needs to be consulted.

Evaluate effectiveness of BMS/EMS/LMS

What does this step mean?

- This step contains 3 sub-steps, but they all have the same purpose: optimizing the current management systems which are in place to make sure the building is operating properly.
 - Evaluate effectiveness: evaluate whether the current management systems are working as they supposed to
 - Perform an analysis to make sure the data quality is good enough
 - Improve the systems

Why do we need it?

- In the Netherlands, 70% of comfort systems are not operating optimally¹. A significant reason for this is that the building management systems are not properly configured. This is logical because during the design of a building, specific occupancy and functions are assumed. However, these often change very quickly, resulting in the building not being tailored to the corresponding function and occupancy.
- An analysis of many building management systems in existing buildings reveals that simply by optimizing the BMS (meaning solve the low-hanging fruit like optimizing the clock-times, optimize institutions) will result in an energy saving of approximately between 5% - 20%².

What are conditions and requirements for its execution?

- The following steps are important for the execution:
 - Make sure the right skills are in place (to optimize a BMS you need specific skills; these are other skills than optimizing a Light management system).
 - Make sure the functionality of the building is clear. What are the opening times, what are the required performances of the building etc. This will be the input to optimize the management systems.

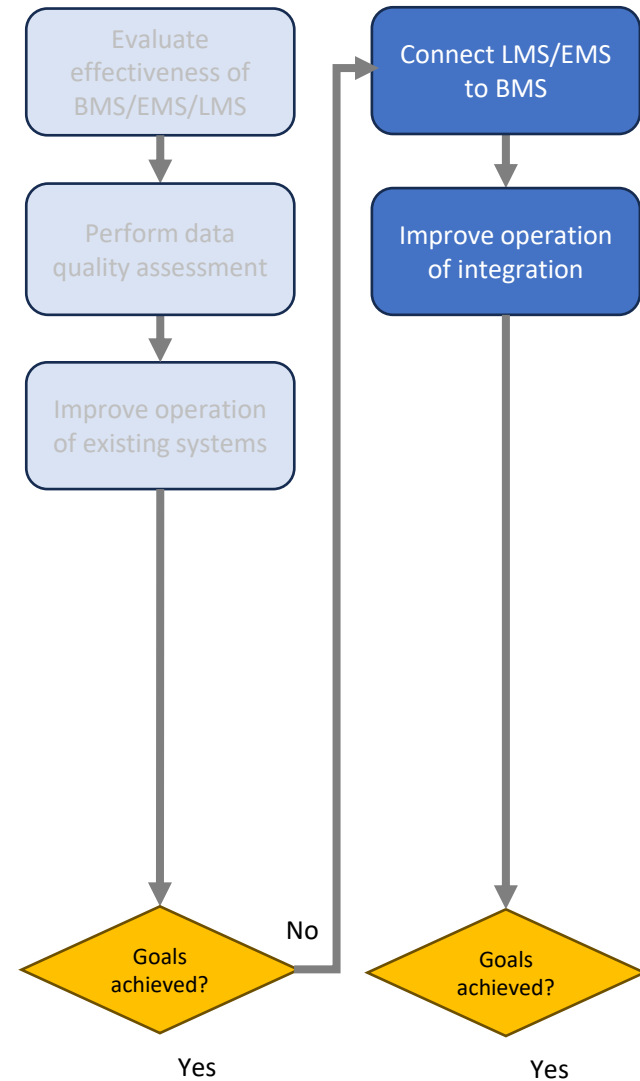

Who needs to do it?

- The hard service provider or the BMS service provider can help you with this step. For specific items (lighting, energy) the specialist needs to be consulted.

¹ [70% van koelinstallaties werkt niet optimaal | \(installatietotaal.nl\)](http://installatietotaal.nl)

² [Energy Efficiency – Lawrence Berkeley National Laboratory \(lbl.gov\)](http://lbl.gov)

Connecting assets

What does this step mean?

- A building has many stand-alone operating systems (burglary installation, light, energy etc.). Connecting these existing systems without ‘adding’ new systems to the building has shown to be a very interesting manner to optimize the building and realize the goal you have.

Why do we need it?

- This step is important because it is a very (cost) effective way to optimize the performance of the building. And therefore, is it a very ‘smart and easy’ step by improving without bringing any new systems into the building.

What are conditions and requirements for its execution?

- To execute this step, it is important to understand what assets you have and how/why you can combine them. This requires knowledge of the individual assets and what they can achieve combined. There are many specialists (hard service provider is one of them) who knows what combinations will create value.

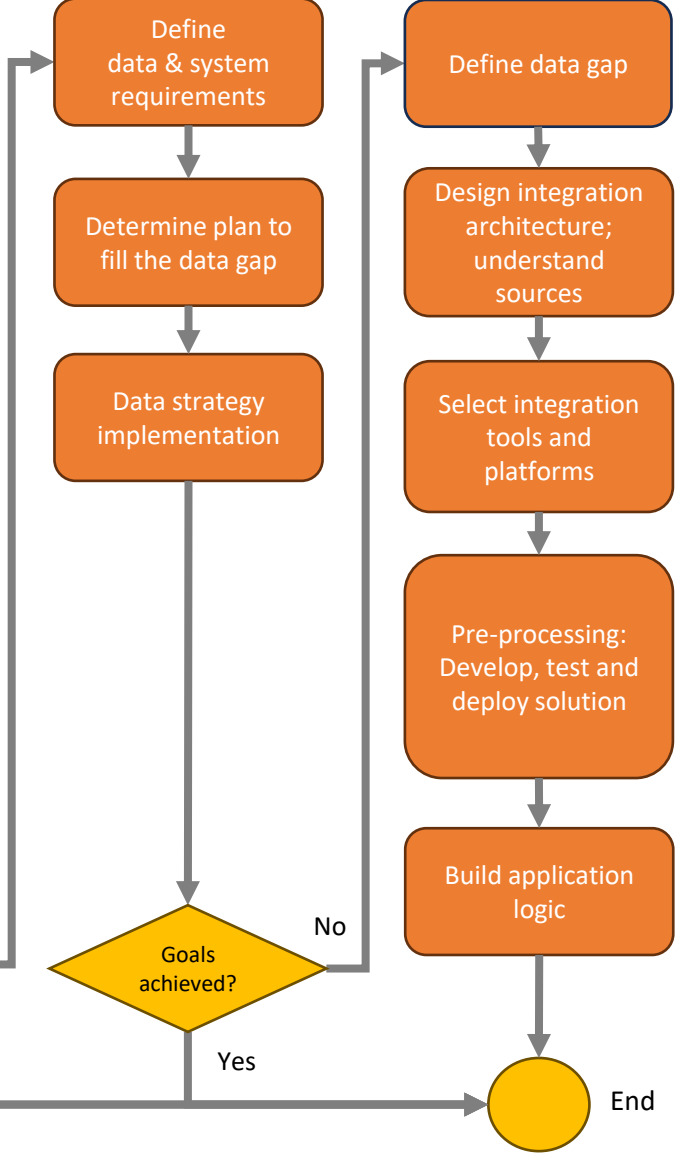

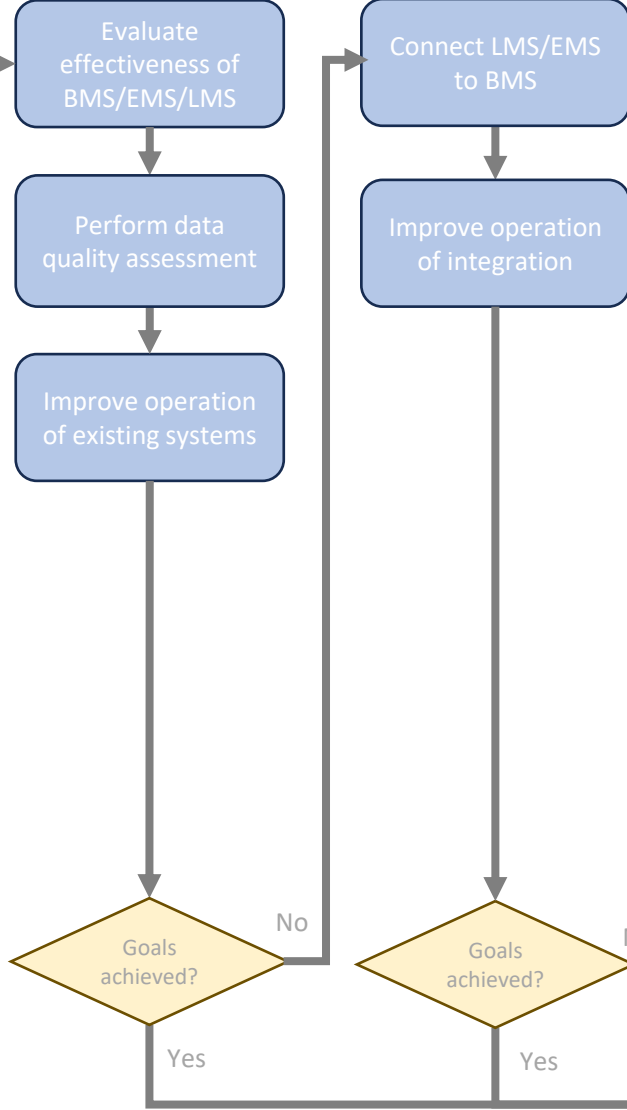

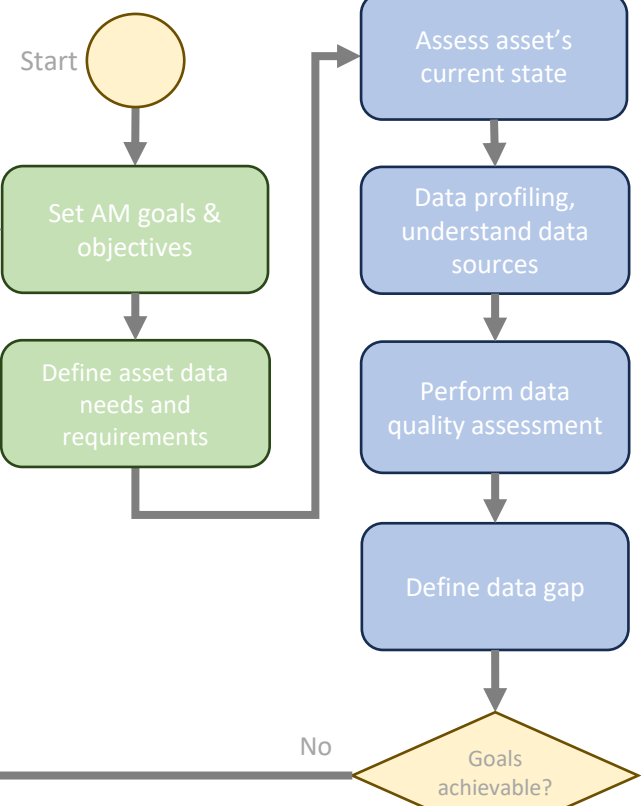

Who needs to do it?

- The hard service provider or the BMS service provider can help you with this step. For specific items (lighting, energy) the specialist needs to be consulted.

Evaluate

Improve

Integrate

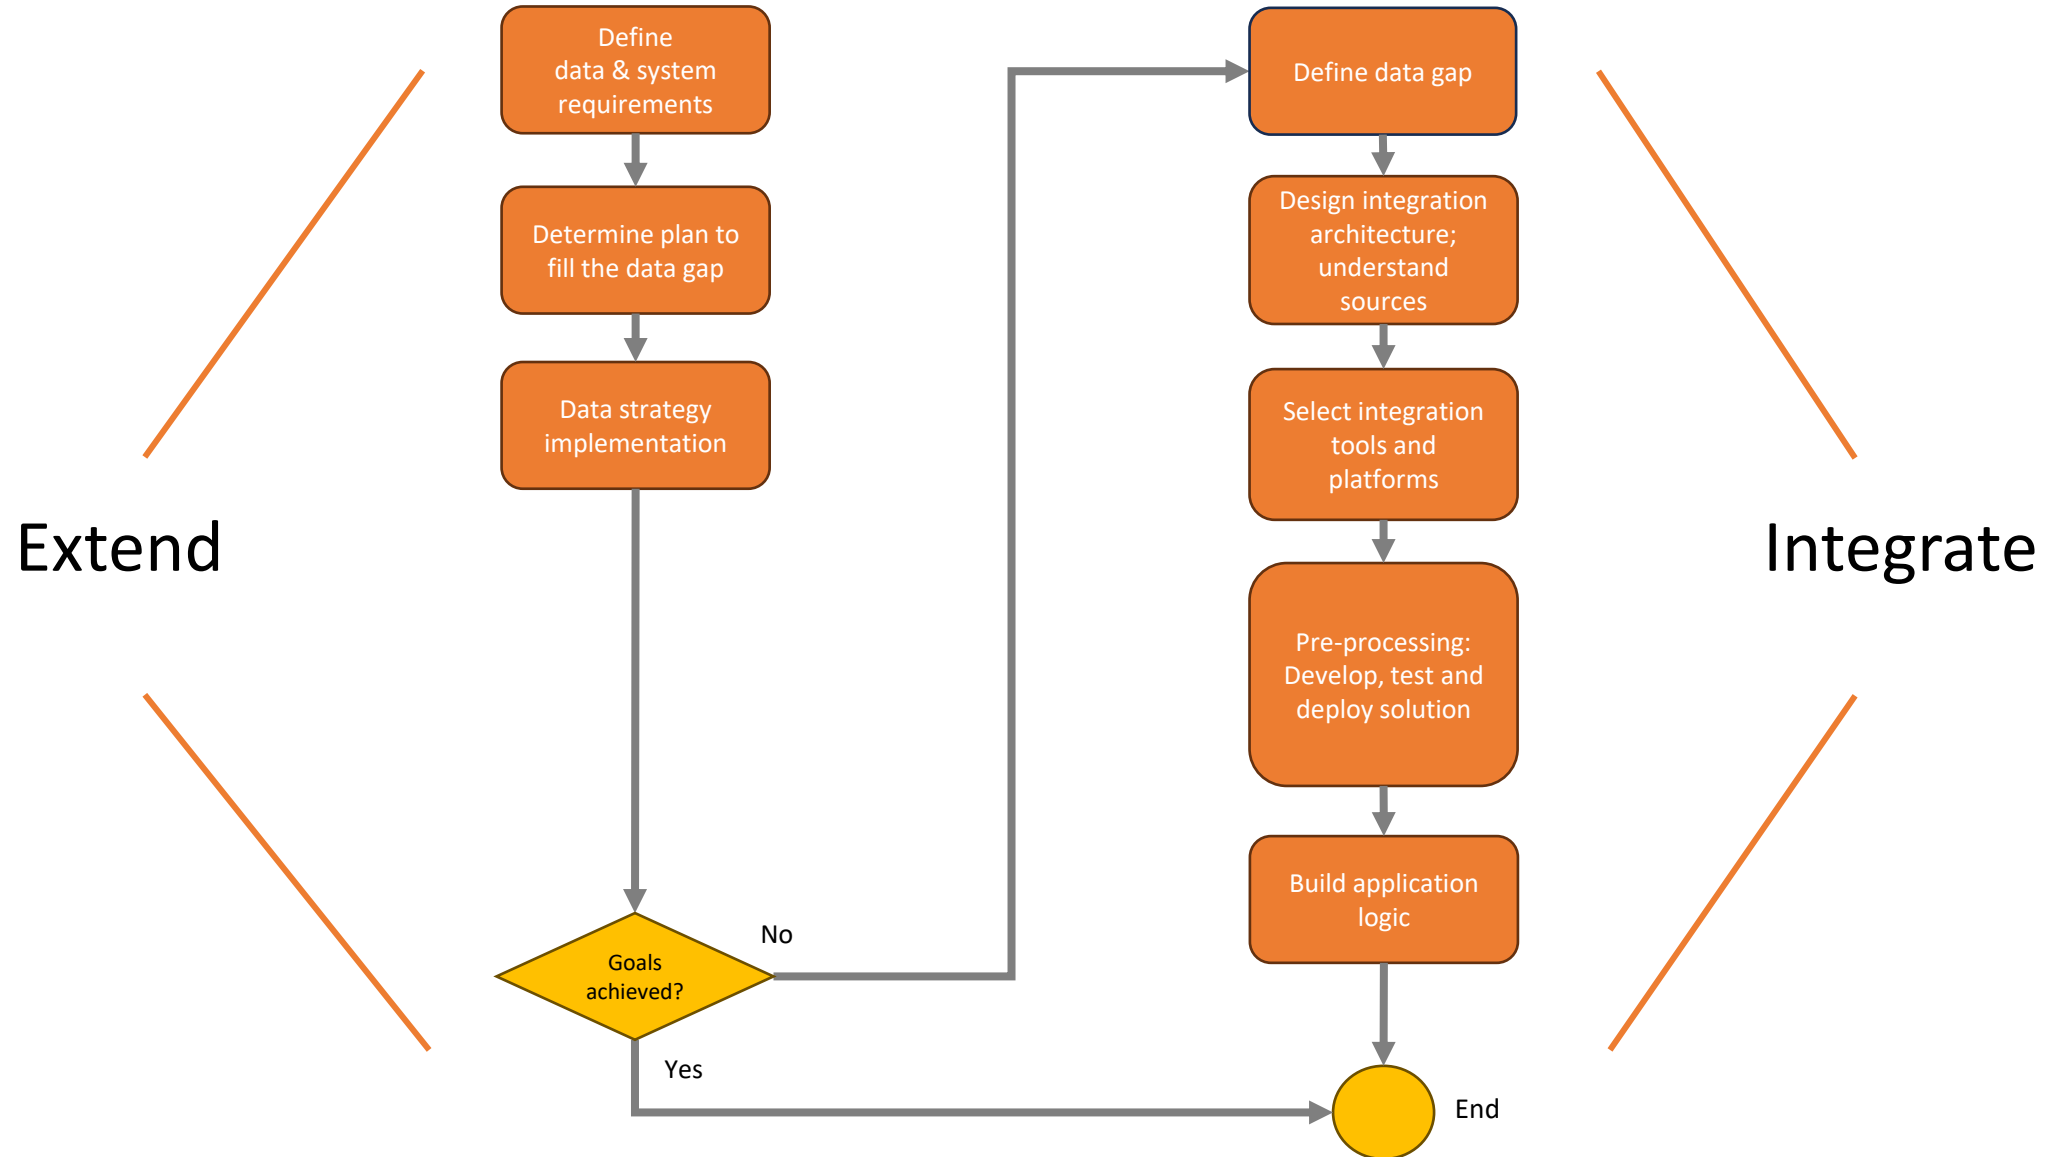

Legend

- Goals (Green box)
- Existing systems (Blue box)
- New systems (Orange box)

New systems

Integrate

Define data & system requirements

Integrate

What

Questions to ask:

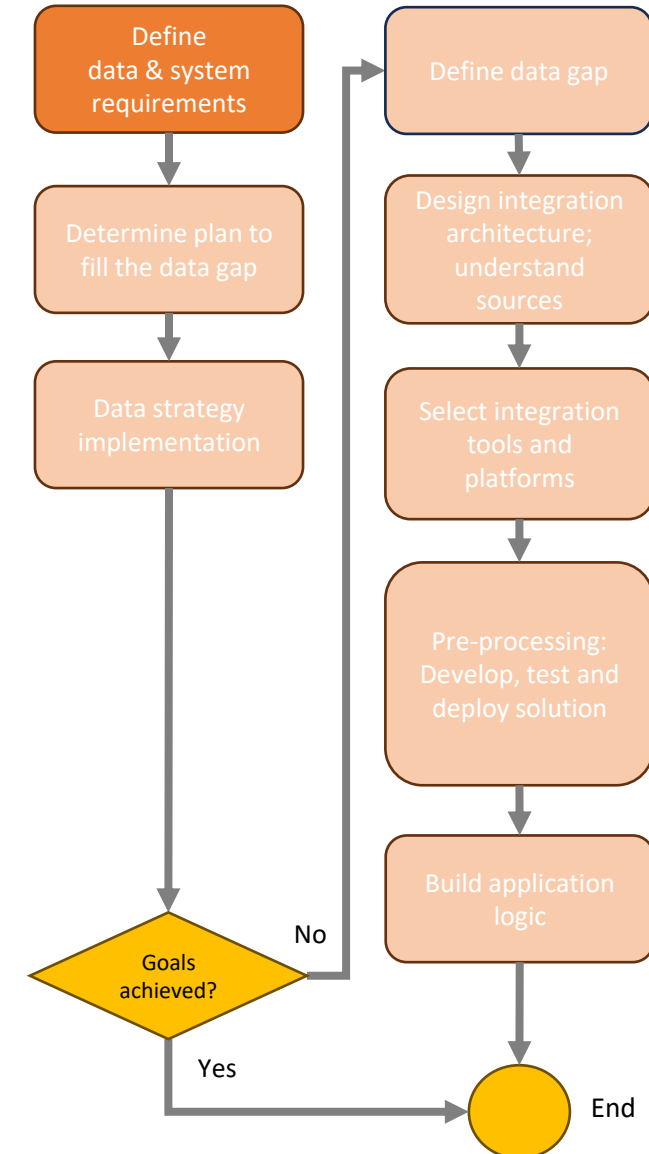

- Which type of sensors/actuators need to be installed?
- Which communication protocol do these sensors use?
- Which communication protocols are supported by my BMS?
- What is the measurement frequency?

Why

System requirements and data requirements

Who

Product developers and consultants, building and facility managers

Install additional monitoring

Integrate

What

Questions which need to be answered:

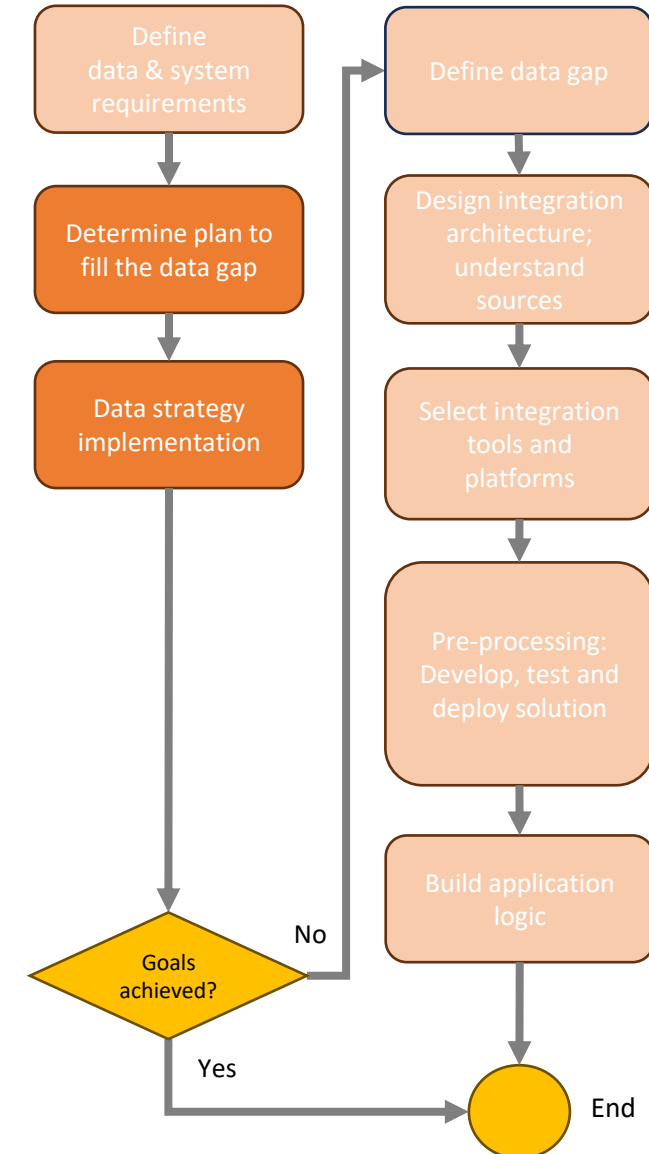

- Where do we install these sensors and control valves?
- What is the prioritization of the identified installations?
- What are the costs involved with filling these gaps?

Why

budget and time constraints.

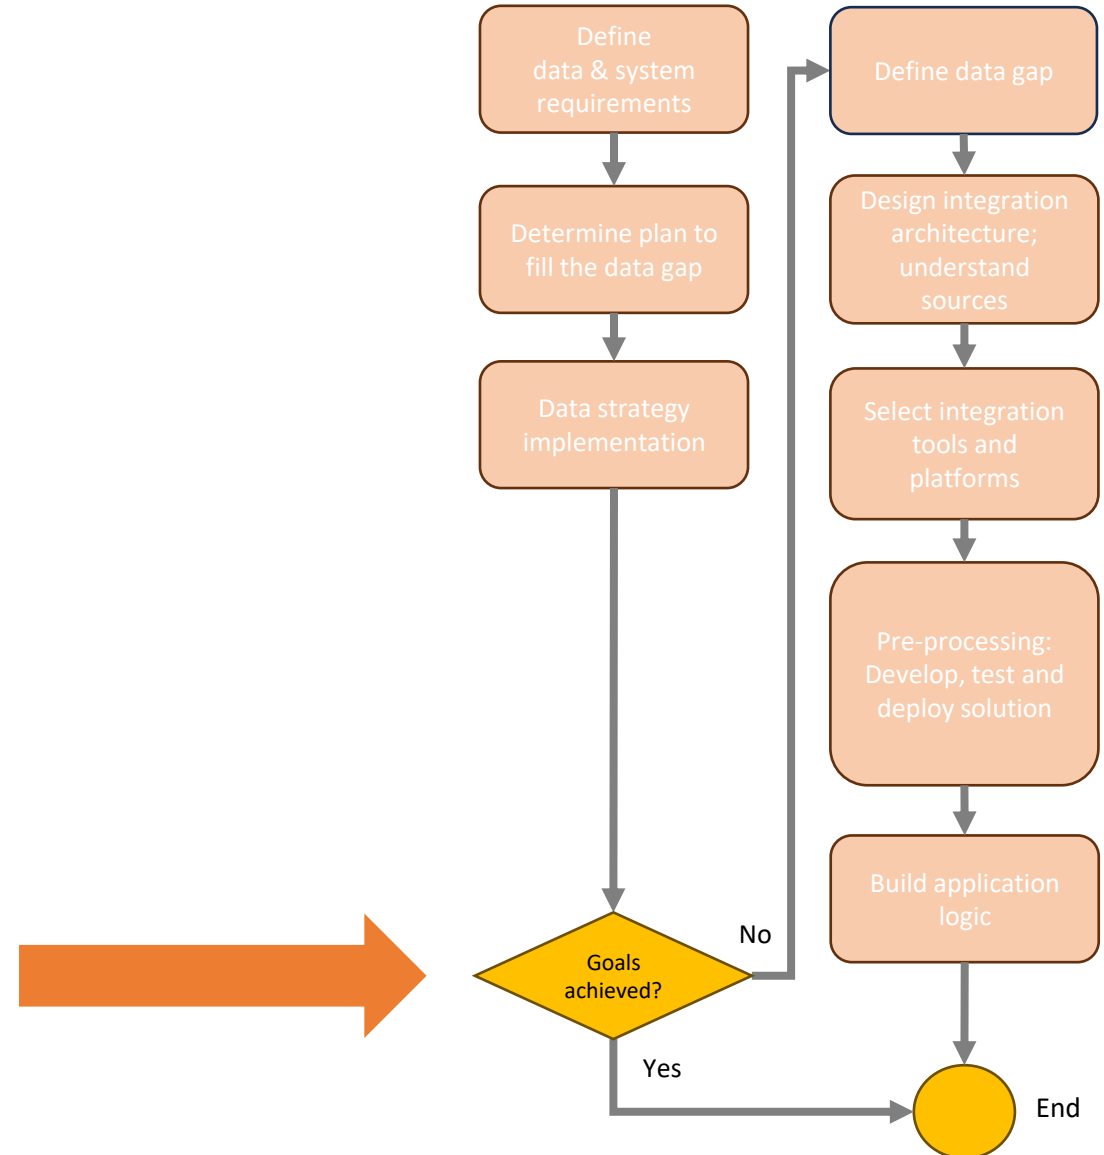

Who

Building- and facility managers, installers.

Install additional monitoring

Integrate

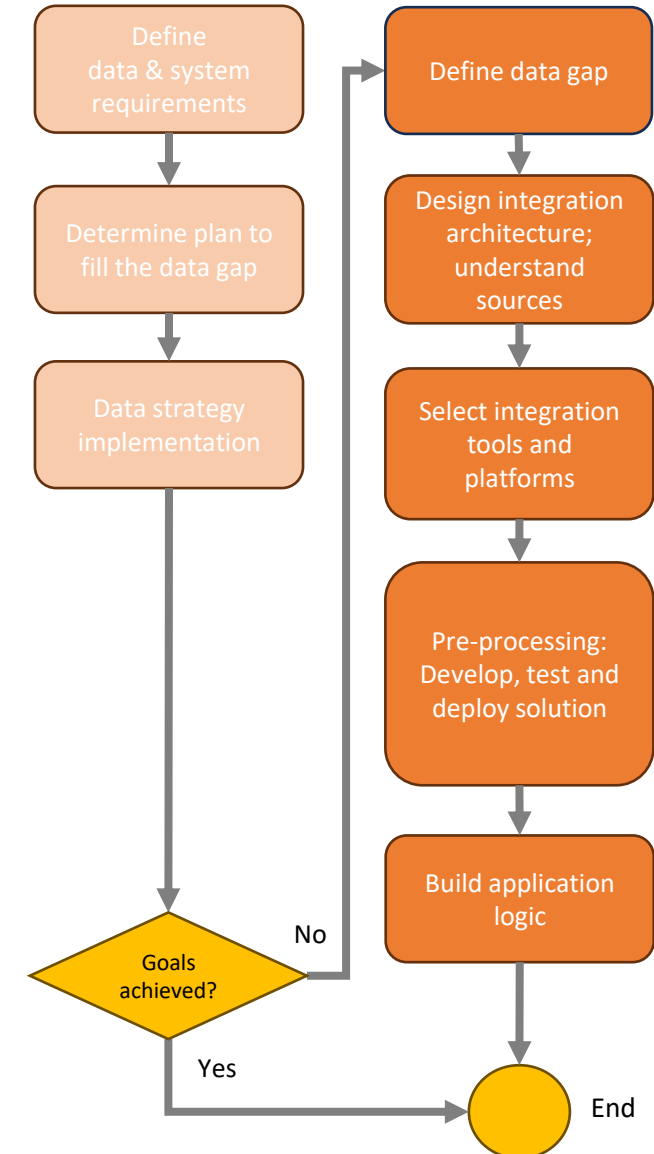

Data integration

Integrate

Operational and contextual data from various sources and systems:

- time series data
- contextual building data (linked data)

Lack of interoperability

Define data gap

Integrate

What does this step mean?

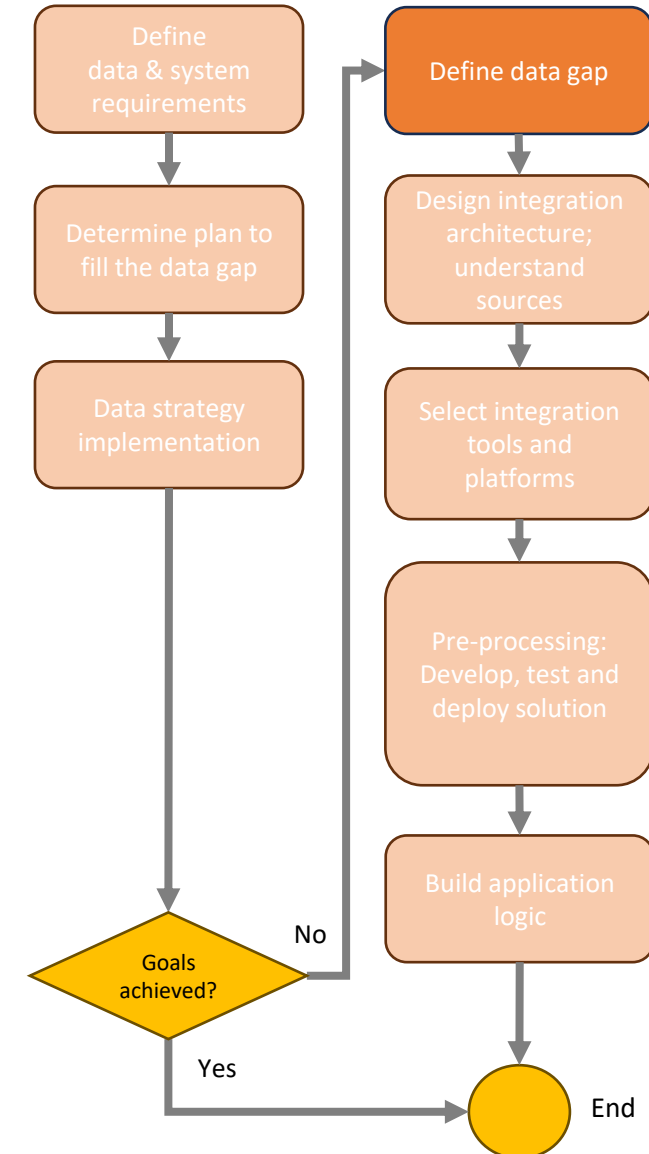

In this step, it is required to think about the asset management goals and how data/information can be used to achieve these goals.

Why do we need it?

Without taking the time to think about the remaining gaps, there is no end goal to work towards while integrating different types of data.

Who needs to do it?

Building- and facility managers, installers

Integration architecture

Integrate

What does this step mean?

Smart buildings need to rely on a well-defined system architecture and Application Programming Interfaces (APIs) that enable both the integration of diverse systems and datasets and the orchestration of various services.

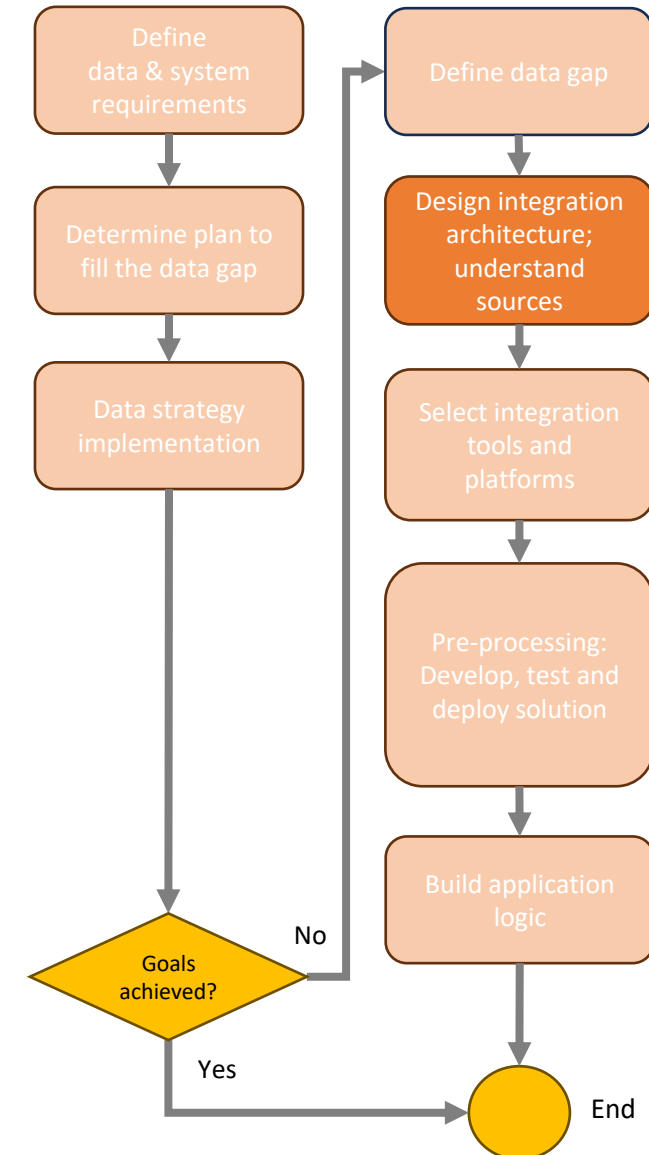

- Choose an appropriate integration architecture (e.g., centralized, decentralized, hybrid) based on the scale and complexity of the BMS.
- Design data flow diagrams to visualize the movement and transformation of data across systems.

Why do we need it?

Each individual building is unique, and path dependency plays a role, so developing a 'one size fits all' system architecture is impossible.

Who needs to do it?

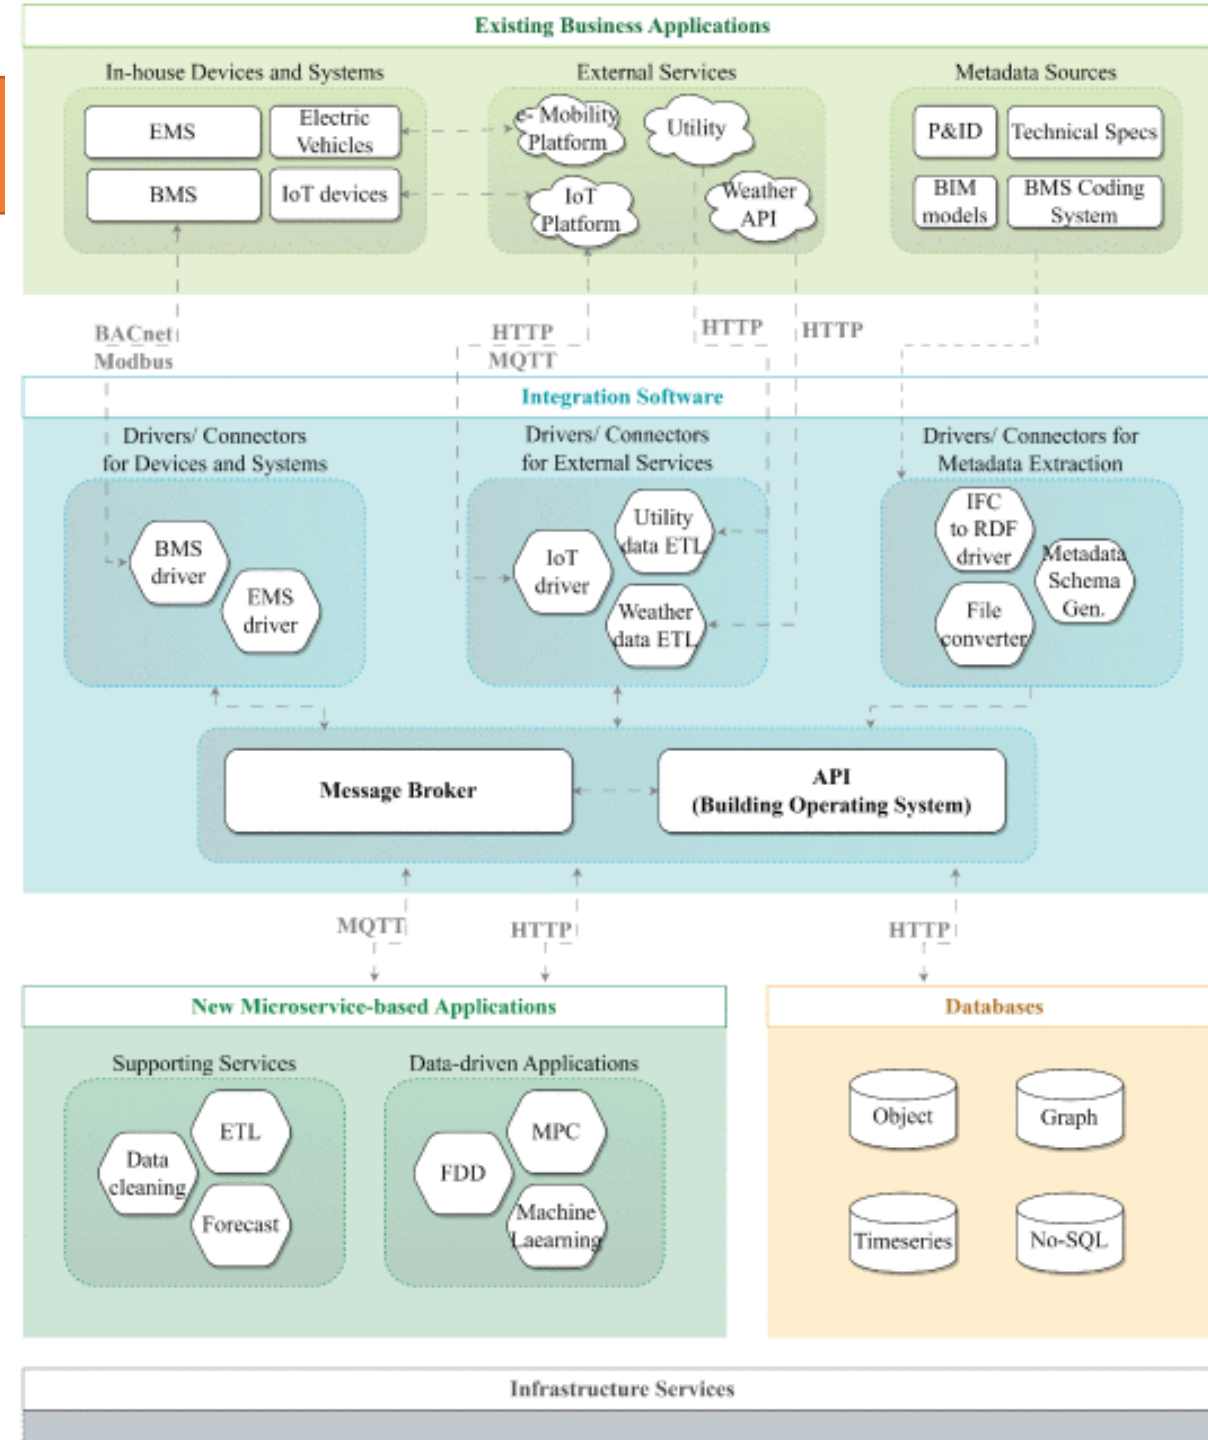

Data(base) engineer, building and facility managers

Reference architecture

The choice of a message broker, time series database, drivers and metadata database should be guided by the specific requirements of the BMS in terms of scalability, performance, data types, and operational environment.

It is also important to consider how these components integrate with each other to create a cohesive data integration ecosystem.

Message broker

Integrate

What

A message broker acts as an intermediary for messaging between different systems or software components.

Why

It enables asynchronous communication, ensuring that messages are queued, delivered, and received reliably.

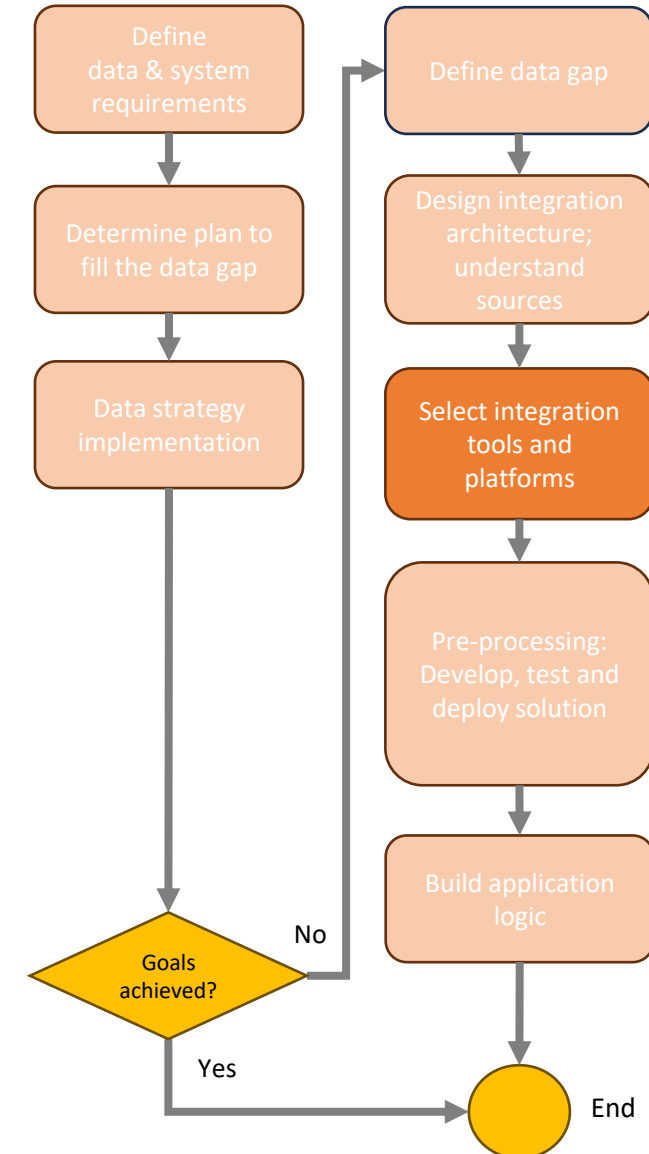

Conditions and requirements

- Scalability
- Performance
- Reliability
- Protocol Support
- Integration Capabilities
- Security

Who needs to do it?

Data engineer

Examples: RabbitMQ, Apache Kafka, MQTT brokers.

Timeseries database

Integrate

What

A time series database is optimized for handling time-stamped or time-series data, such as sensor readings or log data, which is common in BMS.

Why

The previously mentioned message brokers get expensive when the datasets get larger over time. A timeseries database is ideal for storing information for longer periods of time.

What are conditions and requirements for its execution?

- Write and Query Performance
- Data Compression and Storage Efficiency
- Scalability
- Data Retention Policies
- Integration with Analytics Tools
- Reliability and High Availability

Who needs to do it?

Database engineer

Examples: InfluxDB, TimescaleDB, Prometheus.

Driver

Integrate

What does this step mean?

A driver in data engineering serves as an intermediary that translates queries and data operations between the application and the data source, ensuring seamless data access and manipulation.

Why do we need it?

- Interoperability
- Abstraction
- Efficiency
- Standardization
- Scalability

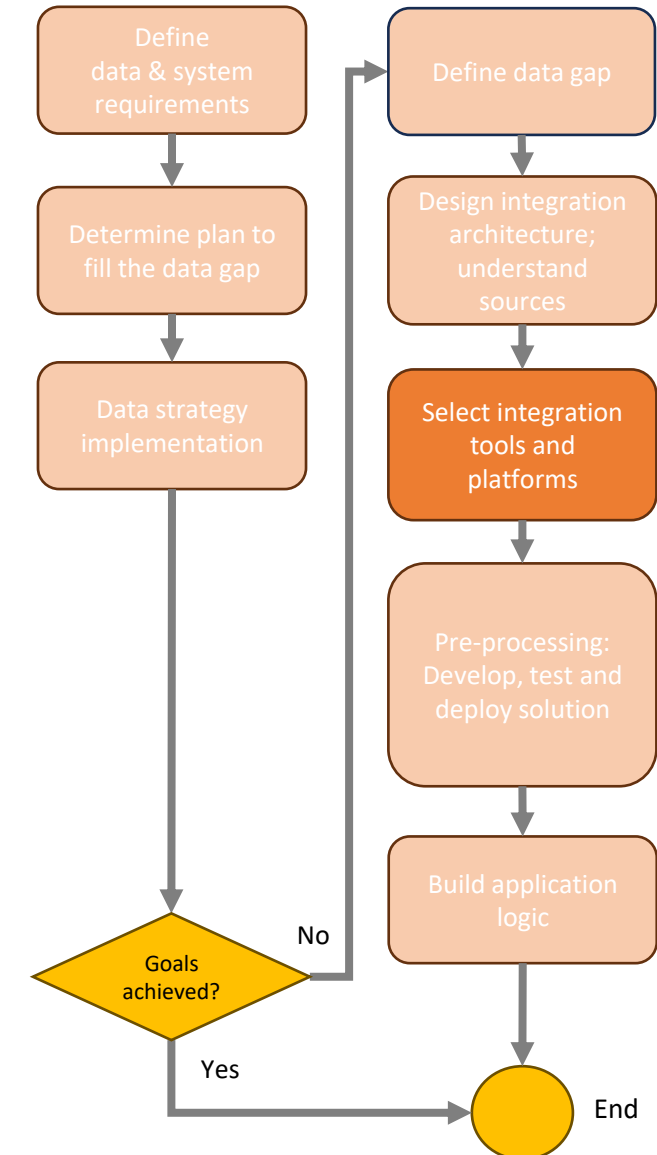

What are conditions and requirements for its execution?

- Compatibility
- Network Accessibility
- Resource Availability

Who needs to do it?

Data engineer

Examples: MySQL ODBC Driver, PostgreSQL JDBC Driver, Apache Kafka Connectors

Metadata database

Integrate

What

A metadata database stores information about other data in the system, such as data source details, schema information, building drawings, and configuration settings.

Why

While a timeseries database is ideal for storing time-stamped data, they are not suited for storing unstructured information. A metadata database is optimized for storing relational information.

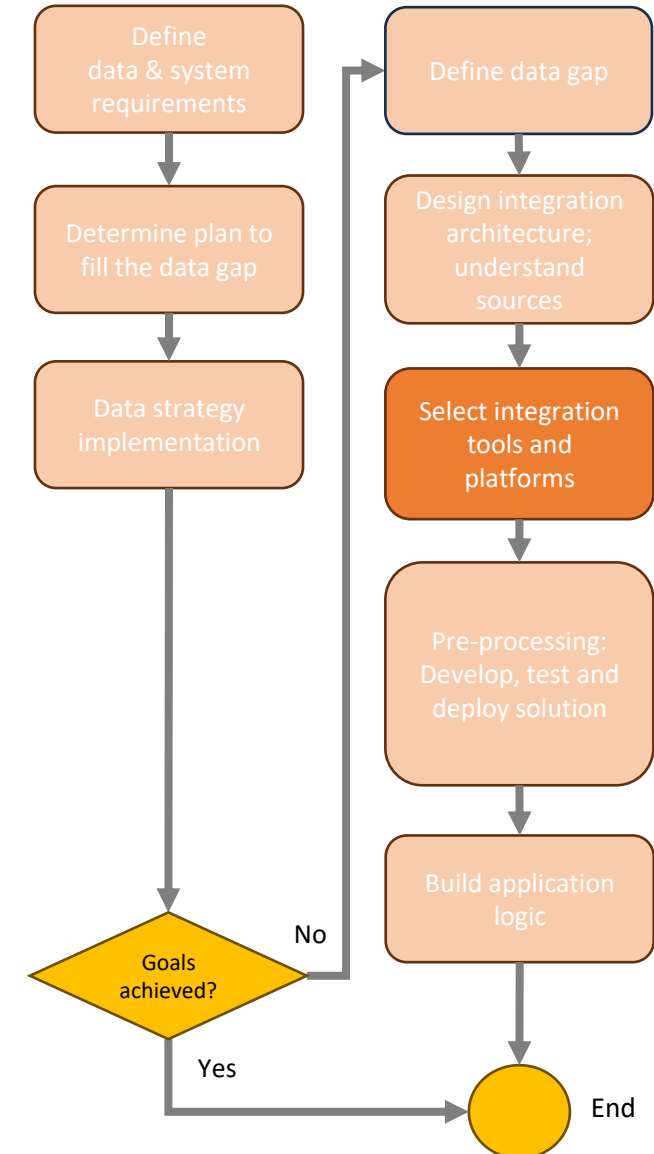

Conditions and requirements

- Schema Flexibility
- Query Performance
- Scalability
- Consistency and Reliability
- Interoperability
- Security

Who needs to do it?

Database engineer

Examples: PostgreSQL (with JSONB support), MongoDB, Apache Cassandra.

Pre-processing

Integrate

What

Before pushing the data to the message broker and database, the data needs to be clean.

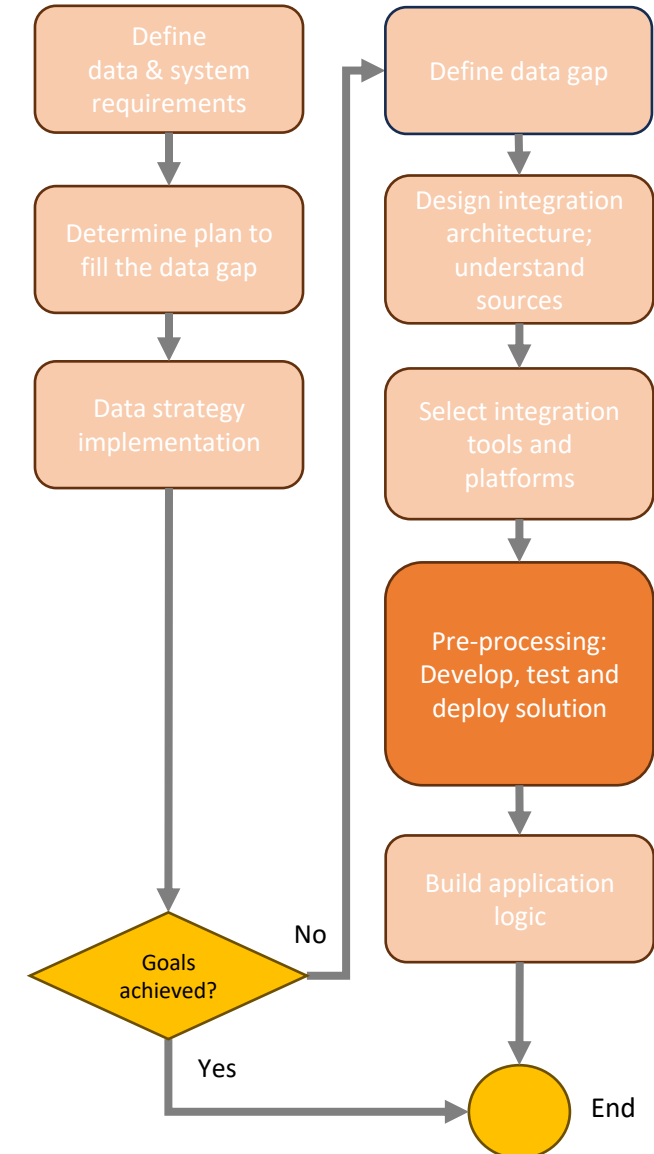

Why

Oftentimes, data is not extracted in the required form. The labels are not intuitive, there is missing data, or the measurements are wrong (outliers).

Who

Data engineer with a building- and/or facility manager.

To dive deeper into the preprocessing, see course by Martin WP5

Data labelling

One of the most common problems in smart building applications is inconsistent data labeling.

different vendors and follow different naming conventions.

Different buildings and systems use diverging standards and conventions.

Unstructured naming conventions and tagging systems to represent data syntax and semantics make it difficult to understand and interpret the data.

Data labelling

Example of naming convention in Johnson Controls

TU Delft sensor naming convention

Missing data

Techniques used for treating erroneous and missing values vary from one application to another:

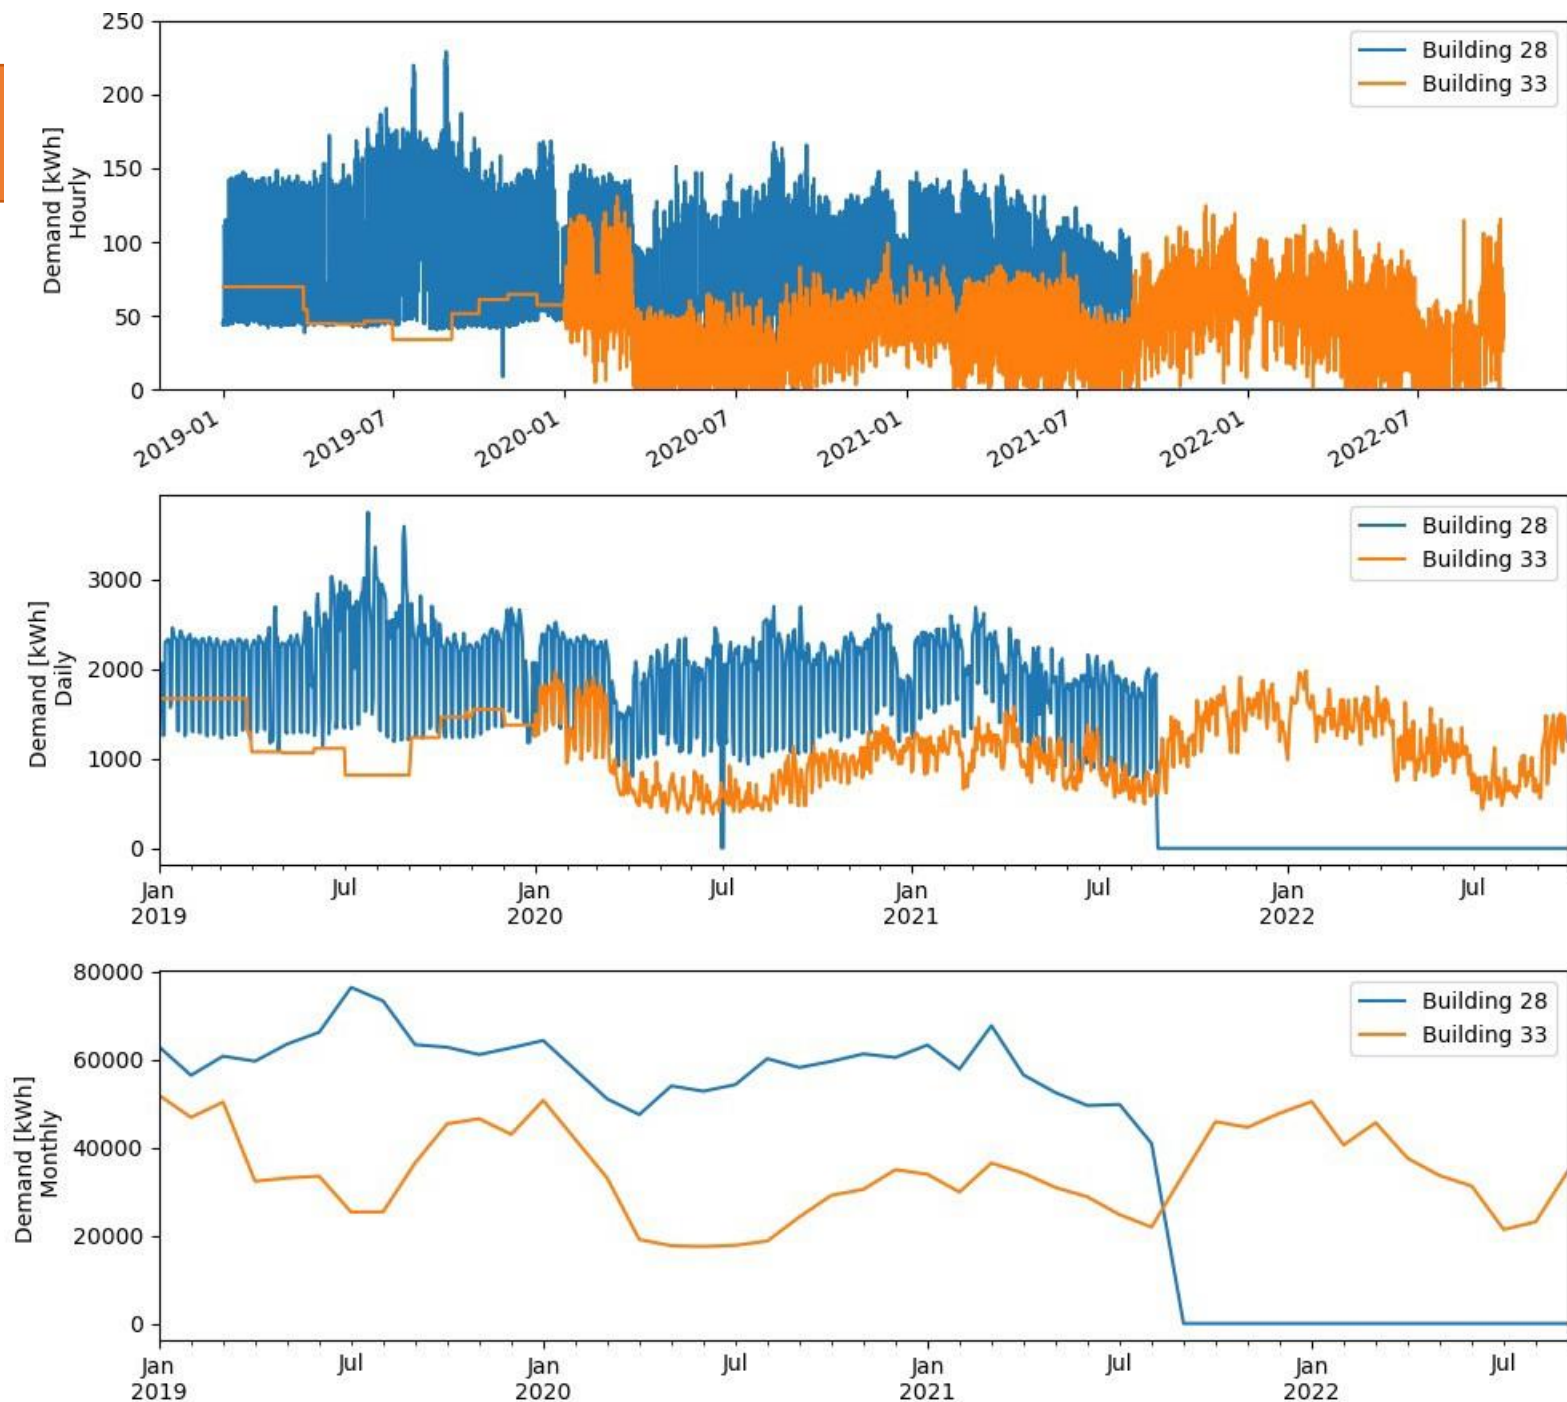

- replacing with next or previous value
- Interpolation
- Rolling average

Downsampling

When gathering frequency does not match the intended application

- Choice of frequency: hourly, daily, monthly, etc.
- Choice of down sampling method
 - Mean: e.g., operating temperature, pressure
 - Sum: e.g., energy demand

Outliers

Removing unexpected outliers to ensure they do not influence the intended application:

- expected range of values (if available)
- Z-scores: need to pick a reasonable value

Integration

What

When the data preprocessing is finished, it can finally be integrated. The data can be pushed to the message broker, which will in turn store the data in the database.

Conditions and requirements

The tools like the message broker, and database need to be in place. Furthermore, the previously mentioned preprocessing needs to be performed on the data to have a proper Extract Transform and Load (ETL) pipeline.

Who needs to do it?

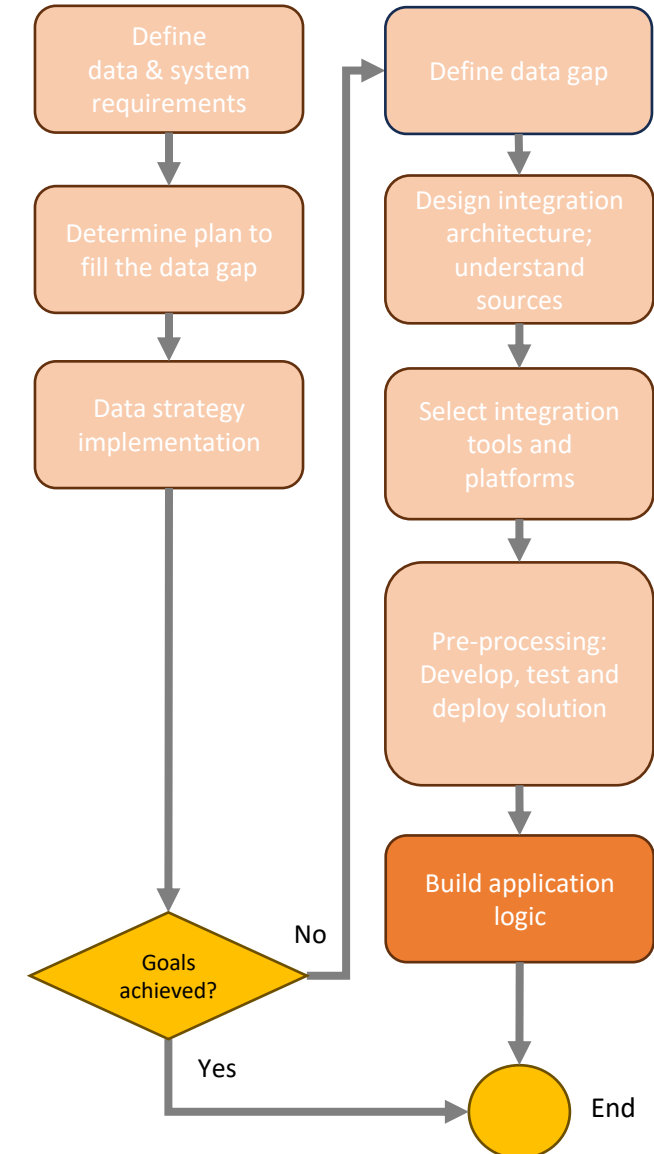

Data engineer

Build application logic

Integrate

This Roadmap is a part of the [Brains for Buildings](#) (B4B) project. This is a multi-year, multi-stakeholder project that aims to develop smart building methods to enhance operations in buildings by reducing energy consumption, increasing energy flexibility, increasing occupant comfort, and improving installation maintenance costs. This will be achieved by developing faster and more efficient Machine Learning and Artificial Intelligence models and algorithms. The project is geared towards existing utility buildings, such as commercial and institutional buildings.

The Brains4Buildings is sponsored by the Dutch grant program for Mission-Driven Research, Development and Innovation (MOOI). This program was established by the Dutch Ministry of Economic Affairs and Climate Change and the Ministry of the Interior and Kingdom Relations and executed by RVO Netherlands Enterprise Agency.
